NUNO Installation and Source Setup

This guide accompanies NUNO.apk and the project source. The target platform is Android. The map, directory, and search can be used offline. Connect to the internet for profile setup and use a connection for the tested location workflow. No password or private API key is required to browse the campus map.

1 Install the APK

Use the NUNO.apk included in this submission. It was extracted from the successful GitHub build for commit 61ec5da. Transfer it to an Android phone, open it, and follow the installer prompts. Permit installation from that source only if you trust this project file. Installation is complete only when Android displays App installed; then tap Open.

A phone may display a Play Protect warning about an unfamiliar developer. For the trusted submission APK, the user may choose the per-app Install anyway option if offered. Do not turn off Play Protect globally. If the installer still reports App not installed, record the phone model, Android version, and message rather than assuming installation succeeded.

If an older NUNO is already installed, a signing-certificate mismatch may prevent an update. This is a possible cause, not a confirmed diagnosis for every failed installation. Removing the old app before a fresh installation clears its locally stored profile and settings. Fresh GitHub debug builds may use a different signing key.

2 Use the Main Features

Search by building, facility, category, or map reference. Switch between Map and Directory. Select a directory row and choose Show on map, or tap a map number or symbol. View in directory opens the matching entry; Fit campus restores the overview.

Connect to the internet before choosing My location for the first time. Complete the student profile with full name, school student number, course, year, and section, then choose Save profile. Verification and registration contact the class API and cannot complete offline. The database id is assigned automatically. This directory is not secure login; do not enter passwords or unrelated personal information.

Keep the connection enabled, turn on device Location, and allow permission when requested. GPS positions are approximate and require field verification. Stop location ends tracking. Settings contains the profile and optional vibration control. Haptics remains unresolved on the tested TECNO phone; visual selection still works.

3 Run the Source Project

Repository: https://github.com/stakatax/nuno. The accompanying NUNO-source.zip contains the committed project and a README.md setup guide. Extract it, install Node.js 24, and open CMD in the extracted folder containing package.json.

Install dependencies:
npm.cmd ci

Start the browser preview:
npm.cmd start -- --host localhost --port 8100

Open http://localhost:8100 and keep the terminal running. Browser testing checks the interface; it does not test native Android vibration. This project uses Angular, Ionic, Capacitor, and Leaflet. No Google Maps key is required.

Build the production web application:
npm.cmd run build -- --configuration production

4 Rebuild the Android APK

Use the Build NUNO APK workflow in GitHub Actions. A push to main starts it automatically; workflow_dispatch allows a manual run. The workflow installs dependencies, applies the haptics helper, builds the web assets, prepares Android, generates icons, adds permissions, synchronizes plugins, and assembles the APK. The hosted build provides the Android SDK and Java toolchain.

Download NUNO-APK under Artifacts from a successful run and extract NUNO.apk. The workflow uses the Android debug build for coursework testing. The helper scripts/fix-android-haptics.cjs targets plugin version 8.0.2. Review it before upgrading that dependency.

5 Data Access and Known Limitations

Basic offline use includes the campus image, directory, and search, which use bundled assets and local records. Profile verification and registration require the online API. First-time My location setup cannot complete without a saved profile. During the offline trial, profile saving and real-time location were unavailable. Offline location with an existing profile still needs testing.

Installation, registration, and basic foreground location passed on the tested phone. While the app was open, it received a GPS position and displayed an outside-map notice with accuracy of about 80 m. This value is position uncertainty, not distance from campus. Another installation failed and haptics remained unavailable on the TECNO phone. GPS is not sent to the student API. On-campus alignment and broader compatibility need further testing.
